6.1 About this chapter

1. General experimental details are listed in Section 6.2.

2. General procedures are used to describe similar reactions performed with various substrates or conditions. These are listed alphabetically in Section 6.3. Solvent amounts are expressed to form a total reaction volume of 10 ml and the final reaction concentration of the main substrate is expressed as concentration (conc.) in moles per litre (M). The amount of the main substrate is defined as one equivalent (1.0 eq.) and the mole amounts of other reagents are expressed in equivalents relative to the main substrate. The variables: temperature, time, reagents, reagent equivalents, solvents and purification methods are quoted as “specified” or as a range when they are not consistent between all procedures and are specified in Section 6.4.

3. Commercially available reagents that were not purchased were synthesised by the procedures in Section 6.4.1.

4. Experimental procedures for compounds described in Chapters 2 and 3 are listed chronologically in Section 6.4.2. Experimental procedures for compounds described in Chapter 4 are listed similarly in Section 6.4.3.

5. Compound names were generated using Name=Struct within ChemDraw 9.0 Ultra. Pictorial representations and references to atoms within discussion text is based on the numbering within the amino acid backbone as depicted in the Nomenclature section preceding this thesis.
6.2 General Details

1. Melting points were determined using a Reichert heating stage with microscope and are uncorrected.

2. Optical rotations were measured using an Optical Activity PolAAr 2001 Automatic polarimeter set at the 589.3 nm sodium D line, in a 0.25 dm cell, at the indicated temperature in the indicated solvent and concentration (c), reported as g solute / 100 ml. Specific rotations, $\alpha_D$, are quoted in $10^{-1}. \text{deg.cm}^2.\text{g}^{-1}$.

3. Infra-red absorption spectra were obtained using a Perkin Elmer 1600 series Fourier Transform Infra-Red (FTIR) spectrometer or a Shimadzu 8400 series FTIR spectrometer and were processed using Shimadzu IRsolution 1.04 software. Compounds were prepared as thin films between 0.5 cm sodium chloride plates seated on a custom made perch in the apparatus. Absorption maxima are expressed as wavenumbers (cm$^{-1}$) and the appearance of bands are described by the abbreviations: br = broad, s = strong, m = medium, w = weak.

4. $^1$H Nuclear magnetic resonance spectra were recorded using a Bruker Avance 200 (200.13 MHz), or a Bruker Avance 300 (300.13 MHz) or a Bruker DPX 400 (400.21 MHz) spectrometer at 300 K unless otherwise specified and were processed using XWIN-NMR version 3.5. Samples were analysed as a solution in the specified solvent. Data are expressed as parts per million (ppm) downfield shift from tetramethylsilane ($\delta_{\text{TMS}} = 0$) using either tetramethylsilane or residual chloroform solvent (7.26 ppm) as an internal reference and are reported as chemical shift ($\delta$), relative integral, multiplicity (s = singlet, br = broad, d = doublet, t = triplet, m = multiplet, q = quartet, quin = quintet, dd = doublet of doublets, ddd = doublet of doublets of doublets, dt = doublet of triplets, ddt = doublet of doublets of triplets, dq = doublet of quartets, obs = obscured), coupling constant ($J$ in Hz) and assignment. All coupling constants and multiplicities reported are apparent. The ♦ denotes resonances from the minor diastereoisomer that differ from the major diastereoisomer in an inseparable mixture.

5. $^{13}$C Nuclear magnetic resonance spectra were recorded using a Bruker Avance 200 (50.0 MHz), or a Bruker Avance 300 (75.5 MHz) or a Bruker DPX 400
Experimental

(100.6 MHz) spectrometer with complete proton decoupling at 300 K unless otherwise specified and were processed using XWIN-NMR version 3.5. Samples were analysed as a solution in the specified solvent. Data are expressed as parts per million (ppm) downfield shift from tetramethylsilane (δTMS = 0) using deuterated chloroform (77.0 ppm) as an internal reference and are reported as chemical shift (δ in ppm). When coupling between a carbon and phosphorus was observed the data are reported as chemical shift (δ in ppm), multiplicity (d = doublet), coupling constant (\(^{13}J_{PC}\) in Hz, where x denotes the number of bonds between the coupled atoms) and assignment. All coupling constants and multiplicities are apparent.

6. Low resolution mass spectra were recorded by the Mass Spectrometry Unit at University of Sydney using positive electron impact (+EI) on a Finnigan Polaris Q ion trap mass spectrometer operated at 40 or 70 eV or using electrospray ionization (ESI) in positive (+ESI) or negative mode (-ESI) on a Finnigan LCQ ion trap mass spectrometer. High resolution mass spectra were recorded by the Mass Spectrometry Unit at University of Queensland using +EI on a Kratos MS25 RFA mass spectrometer operated at 70 eV in magnetic scan using perfluorokerosene (PFK) as standard or by the Mass Spectrometry Unit at Australian National University, Canberra using ESI on a 4.7T Bruker Apex II Fourier Transform Ion Cyclotron Resonance (FT-ICR) mass spectrometer or by the Mass Spectrometry Unit at University of New South Wales using ESI on a 7T Bruker Apex FTICR. Major fragments are quoted as mass to charge ratio (assignment where possible and relative intensity).

7. Analytical high performance liquid chromatography (HPLC) was carried out using a Waters Associates system consisting of a Millipore 510 pump, a Millipore U6K injector, a 2487 dual wavelength absorbance detector at 254 and 270 nm and a 410 differential refractometer. Data were acquired and processed using Empower software. Separation was carried out using the indicated solvents at a flow rate of 1 ml / min on a Jones Zorbax Sil-0201 analytical column with a length of 250 mm, an internal diameter of 4.6 mm and particle size of 5 \(\mu\)m.

8. Preparative HPLC was carried out using a Waters Associates system consisting of a Model 510 pump, a Millipore U6K injector, a 490E programmable multi-wavelength detector at 254 nm and a Millipore R403 differential refractometer. Data were recorded and processed using Empower software.

Retention time ($t_R$) is reported as the time corresponding to the maximum absorbance for the peak detected at 254 nm.

9. Analytical thin layer chromatography (TLC) was performed using 0.2 mm thick, aluminium-backed, pre-coated silica gel plates (Merck Silicagel 60 F$_{254}$). Compounds were visualised by short and long wavelength ultra-violet fluorescence and by staining with a mixture of phosphomolybdic acid and ceric sulfate in sulfuric acid or a solution of ninhydrin in sulfuric acid or an acidified ethanolic solution of anisaldehyde.

10. Flash chromatography was performed using Merck Silicagel 60 (230 – 400 mesh ASTM), under a positive pressure of nitrogen, with the indicated solvents. Solvent compositions were mixed volume per volume (v/v) as specified.

11. Evaporation or concentration under reduced pressure refers to evaporation using a rotary evaporator connected to a water aspirator. Removal of residual solvent when necessary was achieved by evacuation (0.1 – 0.01 mm Hg) with a high stage oil sealed vacuum pump.

12. All solvents and reagents were dried and purified when necessary according to procedures outlined by Perrin and Armarego$^{63}$ or Leonard, Lygo and Proctor.$^{64}$ Commercial $n$-butyl lithium in hexanes was titrated against 2-propanol in tetrahydrofuran using 2,2’-bipyridyl as an indicator. “Hexanes” refers to hexanes (b.p. 65 – 69 °C) and “brine” refers to saturated aqueous sodium chloride solution.

13. Moisture sensitive reactions were carried out in oven dried glassware under a dry inert atmosphere of nitrogen or argon. Powdered, 5 Å molecular sieves were activated in a muffler oven at 500 °C for 3 days and allowed to cool under desiccation before use. Reaction temperatures were controlled using dry ice : acetone (-78 °C), ice : water (0 – 5 °C) cooling baths or sand, oil heating baths (> room temperature).

**Diethyl benzylphosphonate** \(^{76} 106\)

Benzyl bromide (10 ml, 84 mmol) was added drop-wise to stirring triethyl phosphite (16 ml, 93 mmol) at room temperature. The reaction was stirred at room temperature for 45 min, heated at 150 °C for 4 h and allowed to cool to room temperature. The excess of unreacted triethyl phosphite was removed under high vacuum (~ 2 mmHg) to give a clear colourless liquid. Fractional distillation under high vacuum gave pure diethyl benzylphosphonate \(^{106}\) as a clear colourless liquid (13 g, 57 mmol, 68%, b.p. 135 – 137 °C) which was used without further purification in subsequent reactions. For the purposes of characterisation, flash chromatographic purification (40% ethyl acetate : hexanes graded to 100% ethyl acetate) of a small amount of the distilled product gave diethyl benzylphosphonate \(^{106}\) as a clear colourless liquid: \(R_f\) 0.08 (40% ethyl acetate : hexanes); \(v_{\text{max}}\) (thin film) 1250 (br, s, \(\text{R} (\text{R}’\text{O})_2\text{P}=\text{O}\)), 1032, 962 (P-O-C) \(\text{cm}^{-1}\); \(^1\text{H NMR}\) (200 MHz, \(\text{CDCl}_3\)) \(\delta\): 7.12 – 6.99 (5H, m, Ph), 3.88 – 3.70 (4H, m, \(\text{OCH}_2\text{CH}_3\)), 2.92 (2H, d, \(^2J_{\text{PH}}\) 21.6 Hz, \(\text{PhCH}_2\)), 1.00 (6H, t, \(^1J_{\text{PH}}\) 7.0 Hz, \(\text{OCH}_2\text{CH}_3\)); \(^{13}\text{C NMR}\) (50 MHz, \(\text{CDCl}_3\)) \(\delta\): 130.9 (d, \(^2J_{\text{PC}}\) 9.0 Hz, Ph(quot)), 129.0 (d, \(^3J_{\text{PC}}\) 6.5 Hz, Ph(o)), 127.7 (d, \(^4J_{\text{PC}}\) 2.7 Hz, Ph(m)), 126.0 (d, \(^5J_{\text{PC}}\) 3.3 Hz, Ph(p)), 61.2 (d, \(^2J_{\text{PC}}\) 6.7 Hz, \(\text{OCH}_2\text{CH}_3\)), 32.9 (d, \(^1J_{\text{PC}}\) 138.0 Hz, \(\text{PhCH}_2\)), 15.6 (d, \(^3J_{\text{PC}}\) 5.9 Hz, \(\text{OCH}_2\text{CH}_3\)).

(R,E)-tert-Butyl(2,5-dimethylhex-3-enyloxy)dimethylsilane E-165
(R,Z)-tert-Butyl(2,5-dimethylhex-3-enyloxy)dimethylsilane Z-165

The general Julia olefination procedure via premetallation (see page 116) was followed using sulfone 31 (1.5 eq.), potassium bis(trimethylsilyl)amide (0.50 M in toluene, 1.4 eq.) and isobutyraldehyde 88 (0.018 ml, 0.20 mmol, conc. 0.13 M). Solvent = 1,2-dimethoxyethane, T = -60 °C, time_A = 1 h, time_B = 19 h. The crude product was a viscous, off-white liquid (0.19 g). The crude product was analysed by 1H NMR and the ratio of (E)-alkene E-165 to (Z)-alkene Z-165 was determined to be 1.9 : 1 from integration of the C_4-H signals in the spectra: 1H NMR (200 MHz, CDCl_3) δ: 5.25 (1H, dd, J = 15.6, 6.3 Hz, E-165-C_4-H), 4.75 (1H, dd, J = 8.6, 7.1 Hz, Z-165-C_4-H). Flash chromatographic purification (5% ethyl acetate : hexanes graded to 10% ethyl acetate : hexanes) gave pure (E)-alkene E-165 as a viscous clear colourless liquid (0.020 g, 0.082 mmol, 41%): R_f 0.71 (10% ethyl acetate : hexanes); 1H NMR (200 MHz, CDCl_3) δ: 5.41 (1H, dd, J = 15.8, 6.0 Hz, C_5-H), 5.25 (1H, dd, J = 15.6, 6.3 Hz, C_4-H), 3.47 (1H, dd, J = 9.7, 6.2 Hz, C_7-H_A), 3.35 (1H, dd, J = 9.7, 7.1 Hz, C_7-H_B), 2.34 – 2.14 (2H, m, C_6-H, C_3-H), 0.96 (9H, d, J = 6.7 Hz, 3 x CH_3), 0.89 (9H, s, Si-C(CH_3)_3), 0.03 (6H, s, 2 x Si-CH_3); 13C NMR (50 MHz, CDCl_3) δ: 137.3, 129.7, 68.4, 39.2, 31.1, 25.9, 22.6, 18.4, 16.8, -5.3.
The general Julia olefination procedure via premetallation (see page 116) was followed using sulfone 31 (1.5 eq.), potassium bis(trimethylsilyl)amide (0.5 M in toluene, 1.4 eq.) and aldehyde 24 (0.28 g, 0.97 mmol, conc. 0.10 M). Solvent = 1,2-dimethoxyethane, T = -60 °C, timeA = 1 h, timeB = 22 h. The crude product was a viscous, yellow liquid (0.85 g). Flash chromatographic purification (10% ethyl acetate : hexanes graded to 20% ethyl acetate : hexanes) gave a mixture of (E)-alkene E-32 and (Z)-alkene Z-32 in a 1 : 1.5 ratio (determined by integration of the C2-H signals in the 1H NMR spectra: 1H NMR (200 MHz, CDCl3) δ: 4.34 (1H, d, J 3.3 Hz, E-32-C2-H), 4.30 (1H, d, J 3.7 Hz, Z-32-C2-H)) as a clear colourless liquid (0.17 g, 0.37 mmol, 38%).

For characterisation purposes flash chromatographic purification (10% ethyl acetate : hexanes) gave a mixture of (E)-alkene E-32 and (Z)-alkene Z-32 in a 2.5 : 1 ratio (determined by integration of the C2-H signals in the 1H NMR spectra) as a viscous clear colourless liquid (0.023 g, 0.050 mmol, 5%). Data for the (E)-alkene only are quoted where appropriate: Rf 0.44 (20% ethyl acetate : hexanes); 1H NMR (200 MHz, CDCl3) δ: 5.63 (1H, dd, J 15.4, 6.8 Hz, C6-H), 5.47 (1H, dd, J 15.6, 7.0 Hz, C5-H), 4.63 – 4.55 (1H, m, C3-H), 4.34 (1H, d, J 3.3 Hz, C2-H), 3.78 (3H, s, C1-OCH3), 3.53 – 3.33 (2H, m (obs), C7-H2), 2.40 – 2.27 (1H, m, C6-H), 1.62 (3H, s, C(C6H5)(C6H5)), 1.58 (3H, s, C(C6H5)(C6H5)), 1.43 (9H, s, BOC C(CH3)3), 1.00 (3H, d, J 6.8 Hz, C8-CH3), 0.88 (9H, s, Si-C(CH3)3), 0.03 (6H, s, 2 x Si-CH3).
A second fraction gave pure (Z)-alkene Z-32 as a viscous clear colourless liquid (0.033 g, 0.072 mmol, 7%): \( R_f \) 0.47 (20% ethyl acetate : hexanes); \(^1\text{H NMR} \) (200 MHz, CDCl\(_3\) ) \( \delta \): 5.48 – 5.33 (2H, m, C\(_5\)-H, C\(_4\)-H), 4.94 (1H, dd, \( J \) 7.7, 3.7 Hz, C\(_3\)-H), 4.30 (1H, d, \( J \) 3.7 Hz, C\(_2\)-H), 3.79 (3H, s, C\(_1\)-OCH\(_3\) ), 3.64 (1H, dd, \( J \) 9.6, 4.4 Hz, C\(_7\)-H\(_A\) ), 3.38 (1H, dd, \( J \) 9.5, 7.3 Hz, C\(_7\)-H\(_B\) ), 2.77 (1H, br s, C\(_6\)-H), 1.63 (3H, s, C(C\(_A\)H\(_3\))(C\(_B\)H\(_3\) )), 1.59 (3H, s, C(C\(_A\)H\(_3\))(C\(_B\)H\(_3\) )), 1.44 (9H, s, BOC C(CH\(_3\))\(_3\) ), 0.99 (3H, d, \( J \) 6.7 Hz, C\(_6\)-CH\(_3\) ), 0.89 (9H, s, Si-C(CH\(_3\))\(_3\) ), 0.04 (6H, s, 2 x Si-CH\(_3\) ).

A third fraction gave a mixture of (E)-alkene E-32 and (Z)-alkene Z-32 (0.11 g, 0.24 mmol, 25%). The sample decomposed before mass spectroscopy with hydrolysis of the TBDMS group: \textbf{HRMS } (+ESI) calc. for C\(_{17}\)H\(_{29}\)NO\(_6\)+Na 366.1893, found 366.1876; \( m/z \) (+ESI) 366 ([M+Na]+, 100%), 310 (7), 266 (35).
