1 **SUMMARY:**

2 The 6th OARSI Workshop on Imaging in Osteoarthritis combined with the 3rd OA Biomarkers
3 Workshop is the first to bring together the imaging and molecular biomarker communities to
4 focus on clinical validation and qualification of osteoarthritis biomarkers. The workshop was
5 held in Hilton Head, SC, USA, from June 12-14, 2012; 138 attendees participated, including
6 representatives from academia, pharmaceutical and MRI industries, FDA, and NIH.
7 Presentations and discussions raised awareness, consolidated knowledge, and identified
8 strategies to overcome challenges for the development and application of imaging and
9 biochemical biomarkers in OA research studies and clinical trials.

10 **CONCLUSIONS:**

11 The OA research communities need to work alongside regulatory agencies across the world, to
12 qualify and validate new chemical and imaging biomarkers for future research and clinical trials.

13 Key words: Imaging workshop; Osteoarthritis

1 Magnetic resonance imaging (MRI) of knee joints has contributed significantly to the change in
2 perception of osteoarthritis (OA) from wear and tear disease limited to radiographic changes in
3 bone and loss of joint space related to cartilage, to a multi-tissue, whole organ, complex disease
4 with many phenotypes [1]. Aging, obesity, injuries, and an adverse mechanical environment
5 from joint malalignment, can all contribute to OA incidence and progression. The disease may
6 also proceed via different metabolic pathways influenced by race, genetics, and gender.

7 OA is a symptomatic disease associated with characteristic changes in synovial tissue
8 structures. Imaging modalities should reflect this complex phenotype. Although, MRI is a
9 holistic structural assessment modality that provides measures that are the most direct and
10 valid measure of joint status, and the most responsive measure of disease progression [1], the
11 United States Food and Drug Administration (FDA) and the European Medicines Agency (EMA)
12 have yet to accept MRI as an imaging endpoint for OA in clinical trials. Currently, the
13 quantitative measurement of radiography-based joint space width (JSW) is the only accepted
14 imaging endpoint in disease modification efficacy OA trials. Development of disease-modifying
15 therapy has been slowed because radiography has limited capacity to detect clinically
16 meaningful changes in joint morphology that accompany disease progression.

17 The utility of any disease-related biomarker is a function of how well the marker links disease
18 biology and pathology with clinical outcomes. Pain, which along with JSW is a common
19 endpoint in OA clinical trials, appears to at least partly derive from joint tissue alterations
20 (including synovitis, effusion, meniscal pathology, and bone marrow lesions) but associations are
21 generally moderate. Not only do these changes go undetected on conventional radiographs, but
22 pain often antedates radiographic manifestations of disease (Figure 1). Moreover, the
23 structural OA disease process and related pain are dynamic. Such variation in disease
24 progression requires biomarkers that can reflect morphological and pathological changes in
25 joints, beginning in the earliest stages of OA development and progression and throughout the
26 course of disease (see Figure 1). For example, biochemical markers may reflect ultra-structural
27 changes in joint tissue metabolism very early in the disease process prior to any apparent
28 change in imaging appearance on either radiographs or MRI. Similarly, short-term (weeks/
29 months) variation in symptoms is unlikely to be reflected in poorly responsive endpoints such
30 as radiographs.

31 The OA biomarker community has been addressing these and other issues in a series of
32 workshops [2]. Most recently, the OARSI Biomarkers Workshop III – Imaging Biomarker
33 Validation and Quantification organized in conjunction with the 6th International Workshop on
34 Osteoarthritis Imaging, was held July 12 – 14 on Hilton Head Island, South Carolina. More than
35 138 scientists from academia, the government, and the private sector convened for the event.

1 Research presented at the three-day meeting highlighted progress in the field to validate MRI
2 as a biomarker with prognostic and/or diagnostic capabilities.

3 Meeting participants endorsed a plan to facilitate the use of MRI as an endpoint in large-scale,
4 multi-center interventional clinical trials with extended follow-up lasting one and two years, to
5 ascertain the efficacy and safety of different interventions using MRI-based measures as a
6 biomarker of efficacy. In discussing the population on which to base such trials, participants
7 agreed that such a study should, in one instance, focus on recently injured joints; this study
8 paradigm facilitates defining a pathway to OA development and progression because the
9 inciting event and time can be clearly identified (a summary of issues under discussion can be
10 found in Table 1). Meeting participants also emphasized that such trials should utilize imaging
11 technology that could detect differences in the morphological and compositional makeup of an
12 injured joint; detect differences between the injured and uninjured joint; and monitor changes
13 in morphological and compositional makeup over time.

14 Identifying the appropriate imaging modality and parameters will be critical for ensuring
15 responsive, reproducible and reliable outcomes. OA typically progresses very slowly so that the
16 disease can remain at the same structural and clinical level of severity for many years. Without
17 accurate MRI technology, a bone marrow lesion (BML) can be confused with a contusion or
18 subchondral insufficiency fracture, and what looks like a meniscal tear or cartilage lesions can
19 simply be an artifact.

20 An MRI protocol that can assess cartilage quality (e.g. matrix composition) along with
21 morphology and shape measures may help distinguish pathology from normal reparative
22 processes (e.g. increase in cartilage thickness seen after ACL injury could be pathological
23 swelling or adaptive hypertrophy) [3]. Imaging modalities that rely on intravenous contrast
24 administration, which would be useful in assessing synovitis or cartilage proteoglycan
25 (dGEMRIC), may be difficult to use in the current clinical trials and epidemiological studies since
26 they add complexity to the study design and prolong the procedure time; contrast injection
27 necessitates ascertaining adequate renal function prior to injection in order to avoid the very
28 rare contrast medium-induced nephropathy, and entails a waiting period prior to image
29 acquisition.

30 Some of the main drivers in MRI research have been a pursuit of improved metrics for OA trials
31 and their acceptance by regulatory agencies. Although quantitative measurement of cartilage
32 thickness on MRI may have high validity, carrying it forward for trials and clinical use depends
33 on a response from the FDA and the EMA (amongst other world-wide regulatory authorities). In
34 2010, OARSI submitted an analysis to the FDA in which the use of MRI in osteoarthritic joints
35 was detailed. The FDA is actively working to address recommendations necessary to approve

1 MRI parameters as endpoints in clinical trials and this may be facilitated by a formal request for
2 biomarker qualification.

3 In the opinion of some of the meeting attendees, the imaging biomarkers that may be best
4 suited for quantitative measurement of cartilage composition on MRI assessed are T2 and
5 potentially T1rho. Both T2 and T1rho can be implemented and assessed using a software
6 package that could be purchased and standardized across sites [4]. However, there are
7 challenges regarding the reproducibility of T2 and T1rho, and thus these modalities will need to
8 be further standardized before implementation across machines and sites.

9 In all likelihood, any imaging modality utilized as a biomarker will be used in conjunction with
10 biochemical measures. Towards that end, OARSI, as part of an initiative with the Foundation of
11 NIH, has initiated a study using Osteoarthritis Initiative samples to generate data on 12 urine
12 and serum OA biomarkers related to cartilage and bone turnover. Although there's still a need
13 for more specific validation regarding origin, these biochemical measures will be correlated
14 with imaging measures (or outcomes). Urine sampling is not invasive and is particularly valuable
15 for collagen biomarkers; but biomarker levels need to be normalized to urine creatinine to
16 account for the varying hydration states of the individuals. This initiative will provide the
17 opportunity to compare a large cadre of imaging and biochemical markers and to evaluate the
18 potential synergy for these different types of markers singly, and in combination, to reflect
19 disease status and progression.

20 The joint itself can be viewed as a "test tube," with the synovial fluid providing access to
21 proximal information regarding joint tissue metabolites that can be correlated with imaging or
22 histological outcomes. Disadvantages to synovial fluid sampling are several, including:
23 discomfort to the patient, dislike of the procedure by practitioners, requirement for ancillary
24 imaging (ultrasound or computed tomography) for sampling of some joints (such as the hip)
25 and short half-life of some biomarkers in the joint (e.g. the brief half-life of hyaluronic acid in
26 the joint suggests that the concentration of hyaluronic acid changes over minutes). Although
27 there are disadvantages to sampling synovial fluid, in a research setting it can provide the most
28 proximal quantitative data through biomarker analyses of the disease process and thereby can
29 be invaluable for providing biological insights in the disease.

30 Biochemical biomarkers may also help categorize who is at risk and who may benefit from
31 screening for OA by helping detect signal changes linked to OA. Recognizing those patients who
32 will progress rapidly will prove critical in the effort to accurately stage the disease and thus
33 identify people most at risk and most likely to benefit from therapeutic intervention.

34 There is a critical need for imaging methods to evaluate DMOAD activity in a reasonable
35 timeframe, with reasonable sample size, at a reasonable cost. Setting a framework to evaluate

- 1 OA biomarkers that include potential for surrogacy as a major emphasis in modifiable disease
- 2 pathways affecting patient outcomes will identify and advance biomarkers with the greatest
- 3 promise.

1 **Author Contributions**

2 All authors were involved in collecting data, reviewing the literature and drafting the article or
3 revising it critically for important intellectual content, and all authors approved the final version
4 to be published.

5 David Hunter, MBBS, PhD, FRACP, and Ali Guerhazi, MD, PhD, served as meeting chairs. The
6 scientific program committee was comprised of Felix Eckstein, MD, Virginia Byers Kraus, MD,
7 Elena Losina, PhD, and Linda Sandell, PhD.

8 **Acknowledgements**

9 The authors wish to thank science writer Jeanne Erdmann for help in preparation of this
10 manuscript. Ms Erdmann was supported by general funds for the meeting.

11 Support for the meeting was provided by NIAMS Grant number: 5U13AR057296-03. Support
12 was also provided by the Arthritis Foundation, MERCK Serono, Sanofi, Fidia, Orthopedic
13 Research Society, Pfizer, Bioclinica, Boston Imaging Core Lab, Novartis, Piramal Healthcare,
14 QMetrics, Bioiberica, Bioventus, Chondrometrics, Optasia Medical and VirtualScopics.

15 David Hunter is funded by an Australian Research Council Future Fellowship with support from
16 the FNIH OA Biomarkers Consortium.

17 Felix Eckstein is CEO and co-owner of Chondrometrics GmbH. He provides consulting services to
18 MerckSerono, Novartis, Sanofi Aventis, Perceptive, Bioclinica and Abbot.

19 Virginia Kraus is funded by grants from the Foundation for NIH, NIH/NIA Claude D Pepper 5P30
20 AG028716 and NIH/NIAMS 5P01-AR050245.

21 Elena Losina is funded by grants from NIAMS R01 AR053112, K24 AR057827, P60 AR47782.

22 Linda Sandell receives royalties from Millipore.

23 Ali Guerhazi is the President of Boston Imaging Core Lab (BICL) LLC. He is a consultant to Facet
24 solutions, Merckserono, Genzyme, Novartis, and Stryker.

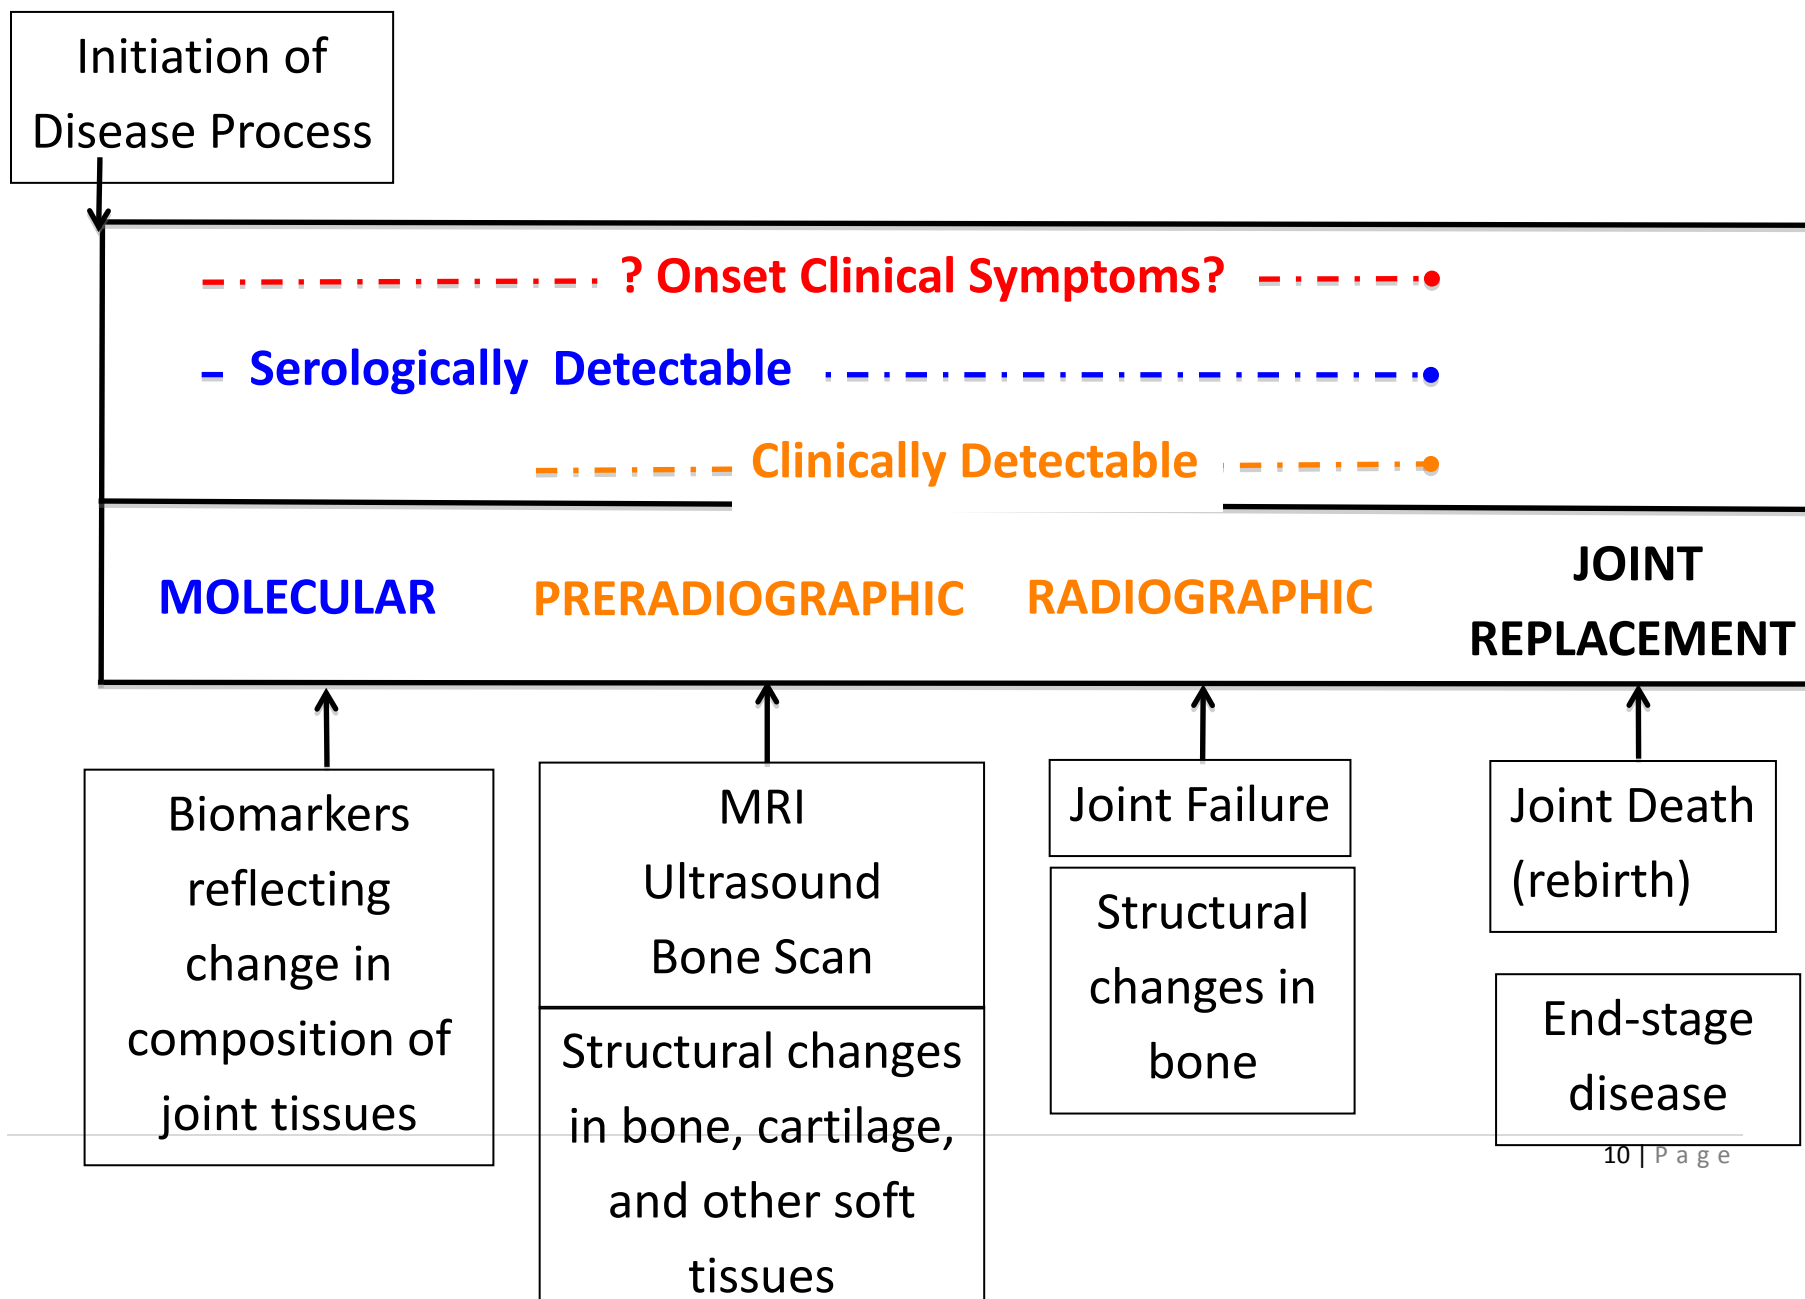

Table 1. Designing the Optimal Trials for Understanding OA. Discussion and Future Directions	
Discussion Points	Suggestions
Determine imaging modalities for longitudinal multi-center injury trials.	Use T2 as basis assessment of joint morphology and then T1rho as background if this modality can be standardized.
Establish standard measurement parameters on imaging (a core-set).	For example of cartilage composition, cartilage lesions and cartilage thickness, shape measures need to be collected to determine effect and which best predicts long term clinical outcome
Determine best strategy for regulatory bodies to generate different guidance criteria for different phases of clinical trial intervention.	Include MRI with all the other endpoints in early phase trials (especially Phase 2), and then determine if you can use it later as a primary endpoint based on the study. Modify requirement for 30-50% reduction in JSW as a threshold for evidence of successful structural modification as no single drug will impact readily this parameter.
Identify which structural changes are most specifically associated with clinical endpoints in (knee) OA, and hence need to be treated.	Reach a consensus on standardized clinical endpoint so studies are easier to compare. Explore utility of virtual total joint replacement (TJR) as a potential endpoint in future clinical trials.
Determine histopathological relationship among structural changes to cartilage and subchondral bone and 'soft' tissues of the articular organ that can be seen on MRI. (Joint tissue- MRI structure correlation)	Match treatable pathology with appropriate imaging methodology.
Monitor patients for damage in other joints especially when treated by highly effective analgesics; any damage needs to be detected early.	Some suggested methods of determining risk include asking patients about pain levels; radiographic screening; joint specific biochemical markers.
Determine whether quantitative MRI, either morphometric, compositional or semi-quantitative as an endpoint, is a suitable method to be used in cartilage repair trials and for long term follow up.	Need to measure local changes in collagen/GAG and quantitative MRI for morphology suitability but success of the intervention is determined by the long term outcome for the whole joint.
Establish imaging criteria that will label cartilage repair procedures successful from a	MRI (as opposed to arthroscopy) may not be the most suitable outcome for assessing the
